Summary

During an era of oil price controls and following the 1973 Organization of Arab Petroleum Exporting Countries oil embargo, Congress passed the Energy Policy and Conservation Act of 1975 (EPCA), which directs the President “to promulgate a rule prohibiting the export of crude oil” produced in the United States. Crude oil export restrictions are codified in the Export Administration Regulations administered by the Bureau of Industry and Security (BIS)—a Commerce Department agency. The President has some powers to allow certain crude oil exports if an exemption is determined to be in the national interest.

In 2009, a decades-long U.S. oil production decline was reversed due to the application of advanced drilling and extraction technologies to produce tight oil. The Energy Information Administration (EIA) 2014 reference case projects that total U.S. crude production will be 9.6 million barrels per day by 2019—up from 7.7 million in 2013. Nearly all of this growth is expected to come from tight oil production. This anticipated growth is resulting in calls to lift or otherwise ease U.S. crude oil export restrictions. However, crude oil imports are projected to range from 6 million to nearly 8 million barrels per day for the period out to 2040. This apparent disconnect between import needs and the desire to export can be explained when considering the following: (1) geographic location of tight oil, (2) tight oil quality characteristics, (3) refinery configurations, (4) oil transportation network, and (5) price discounts in different regions.

EIA’s reference case also projects that tight oil production will decline after 2019, raising questions about the potentially temporary nature of the export opportunity. However, EIA’s high-growth case projects tight oil production growth out to 2040. There is a degree of uncertainty associated with long-term tight oil projections.

Tight oil produced in the United States is generally of the light/sweet (low sulfur) variety, referred to as light tight oil (LTO). Expected LTO volumes could potentially result in an oversupply of light crudes in certain regions, such as the Gulf Coast where refineries are currently configured to process heavy/sour crudes and yield certain volumes of specific oil products (e.g., diesel and gasoline). Timing for a potential LTO oversupply situation is uncertain. Some analysts estimate that it could occur as early as 2015. However, the oil industry is dynamic. It will adjust based on market and economic considerations (e.g., price discounts, product values, and investment requirements). For example, refineries can add equipment to process additional light crude volumes. Transportation modes (i.e., pipeline, rail, and marine vessels) can adapt to deliver LTO to refineries throughout the country. While investments in equipment could allow refiners to process more LTO, economic considerations will likely dictate how much additional LTO will be absorbed domestically. Condensate, an extra-light hydrocarbon, is of particular concern to some oil producers because of its limited domestic marketability, increasing production volumes, and inclusion in the BIS crude oil definition.

There are several issues that Congress may consider associated with exporting U.S. crude oil. Of particular interest may be how allowing exports might affect crude oil prices. These effects are likely to be threefold: (1) domestic prices for exported oil will likely converge towards the world price, (2) U.S. benchmark prices will likely adjust to world prices, and (3) world prices will likely adjust to reflect added supplies. The magnitude of these price effects will depend on export volumes. Product price (i.e., gasoline) effects may be mixed and could differ by region. Additional considerations that may be of interest to Congress might include potential impacts on energy security, geopolitics, international trade, and the environment.

Multiple crude oil export policy options might be considered that range from lifting current export restrictions to maintaining export restrictions. Additionally, there are several other policy options that might include exempting LTO from export restrictions, modifying the BIS crude oil definition, or allowing crude oil exports for a limited period of time.

Introduction

As a result of advanced oil drilling and extraction technologies (primarily horizontal drilling and hydraulic fracturing), crude oil production in the United States is growing and, according to Energy Information Administration (EIA) reference case projections, may reach 9.6 million barrels per day (bbl/d) by 2019—up from 5 million bbl/d in 2008 (see **Figure 1**).¹ Production of light tight oil (LTO) is, and is expected to be, the primary contributor to U.S. crude oil production growth in the near to medium term. As U.S. LTO production has increased, some have called for crude oil export restrictions to be either eased or lifted altogether.² However, according to the Energy Information Administration (EIA), U.S. crude oil demand is forecasted to be approximately 15 million bbl/d through 2040.³ According to EIA's reference case, crude oil imports are projected to range between 6 million and 8 million bbl/d over the same period.⁴ Although, EIA's high resource case projections, if realized, could result in lower import requirements. This apparent disconnect between expected import needs and the desire to export crude oil can be explained when considering the following: (1) the geographical location of LTO production, (2) the type/quality (i.e., light, sweet) of crude oil being produced, (3) the types of crude oil that some U.S. refineries are currently configured to optimally refine, (4) the petroleum products that are derived from different types of crude oil, and (5) transportation and infrastructure challenges associated with moving certain types of crude oil to demand centers. Each of these aspects is discussed in more detail throughout this report.

Source: Energy Information Administration, Annual Energy Outlook 2014 Reference Case Early Release Overview.

While U.S. crude oil exports are restricted under current law, petroleum products such as naphtha⁵, gasoline, diesel fuel, and natural gas liquids are not subject to export restrictions. As a result, production and export of these products have increased in recent years. In October 2013, approximately 3.8 million barrels per day (bbl/d) of petroleum products were exported from the United States—up from an average of nearly 1.4 million bbl/d in 2007.⁶

Members of Congress have taken various positions regarding crude oil exports, including (1) calling for the Administration to lift export restrictions,⁷ (2) maintaining existing restrictions,⁸ and (3) opposing attempts to lift restrictions through the World Trade Organization.⁹

The crude oil export policy debate has multiple dimensions and complexities. As U.S. LTO production has increased—along with additional oil supply from Canada—certain challenges have emerged that affect some oil producers and refiners. While the economic arguments both for and against U.S. crude oil exports are quite complex and dynamic, there are some fundamental concepts and issues that may be worth considering during debate about exporting U.S. crude oil.

⁵ Naphtha is a refined or partially refined light hydrocarbon that is blended or mixed with other hydrocarbons to make motor gasoline or jet fuel. Naphtha can also be used as a solvent or petrochemical feedstock. For more information, see EIA glossary at <http://www.eia.gov/tools/glossary/>, accessed March 12, 2014.

⁹ Senator Edward Markey, Letter to Ambassador Michael Froman, U.S. Trade Representative, December 3, 2013.

This report provides background and context about the crude oil legal and regulatory framework, discusses motivations that underlie the desire to export U.S. crude oil, and presents analysis of issues that Congress may choose to consider during debate about U.S. crude oil export policy.

Background

Current crude oil export restrictions date back to the 1970s, during an era of U.S. oil price controls that motivated producers to export and sell crude oil at unregulated world prices.¹⁰ In response, crude oil, petroleum products, and natural gas liquids were placed on the Commodity Control List established by the Export Administration Act of 1969.¹¹ In 1973, the Organization of Arab Petroleum Exporting Countries (OAPEC) imposed a total embargo of crude oil delivered to the United States.¹² The oil embargo motivated Congress to enact laws that would limit U.S. crude oil export opportunities.¹³ The embargo resulted in rapid and steep crude oil price increases, thereby creating a perception of oil resource scarcity and prompting concerns about U.S. crude oil import reliance.¹⁴ In response to these concerns Congress passed legislation—including the Energy Policy and Conservation Act (EPCA)—to restrict U.S. crude oil exports, with some exceptions as determined by the President. Using these exceptions, the United States has exported crude oil for decades, although in relatively low volumes. Crude oil exports reached a level of 287,000 bbl/d in 1980.¹⁵ In 2013, crude oil exports from the United States averaged 120,000 bbl/d, almost all of which was sent to Canada.¹⁶

In the context of exports, the Bureau of Industry and Security (BIS)—the Department of Commerce agency responsible for crude oil export licenses—defines “crude oil” as follows:

“Crude oil” is defined as a mixture of hydrocarbons that existed in liquid phase in underground reservoirs and remains liquid at atmospheric pressure after passing through surface separating facilities and which has not been processed through a crude oil distillation tower. Included are reconstituted crude petroleum, and lease condensate and liquid hydrocarbons produced from tar sands, gilsonite, and oil shale. Drip gases are also included, but topped crude oil, residual oil, and other finished and unfinished oils are excluded.¹⁷

From 1970 to 2008, U.S. crude oil production was on a steady decline (see **Figure 1**). During this time, there were periods when easing crude oil export restrictions was a national-level policy

¹⁶ *Ibid.* Some non-U.S. crude oil was re-exported to China in 2013. Re-exports of non-commingled foreign crude oil are allowed under current export restrictions.

¹⁷ U.S. Department of Commerce Bureau of Industry and Security, “Export Administration Regulations: Short Supply Controls,” February 28, 2013.

topic and presidential determinations were made to exempt crude oil exports that met certain criteria. In 2009, production of light/sweet crude in tight oil formations throughout the country started to increase rapidly, and production levels are expected to continue rising out to 2019, or perhaps later.

The physical and chemical properties of LTO, when placed into context of the crude oil slate¹⁸ desired by U.S. refineries, is one important factor that underlies the crude oil export debate. For more information about crude oil characteristics, see the text box below.

All Crude Oil Is Not Created Equal

Hundreds of different types of crude oil are produced globally, each of which has unique qualities and characteristics. Two of the most common parameters used to compare different types of crude oil are (1) API gravity, and (2) sulfur content. API gravity, expressed in degrees, indicates the density of crude oil. The higher the API gravity, the lighter the crude oil. Sulfur content, expressed as a percentage, indicates the amount of sulfur contained in a particular crude stream. High sulfur content crudes are referred to as “sour” and low sulfur content crudes are referred to as “sweet.”¹⁹ Additionally, when processed by a refinery, different crude oils can yield varying amounts of petroleum products such as gasoline, diesel fuel, jet fuel, and fuel oil. The following table compares five different types of crude oil based on API, sulfur content, and initial product yield.

Crude Oil (Yr)	API°	Sulfur (%)	Initial Product Yield (%)				
			Resid	Gas oil	Distillate	Naphtha	Other
Maya ('07)	20.5 (H)	3.65 (Sr)	36	14	21	18	1
Arabian Heavy ('01)	27.5 (H)	2.78 (Sr)	30	25	24	18	3
Eagle Ford Cond. ('11)	55.6 (XL)	0.01 (Swt)	1	15	31	48	5
Eagle Ford 40 ('12)	40.1 (L)	0.09 (Swt)	11	28	33	26	2
West Texas Sour ('01)	32.4 (M)	1.72 (Sr)	14	29	29	27	1

Source: API and Sulfur numbers from EIA; Product Yields from Chevron Assays.

Notes: Product yields represent typical initial yields off atmospheric and vacuum towers, which is generally the first step in the refining process. Additional processing steps (i.e., cracking, coking, combining, etc.) are used to produce finished products such as gasoline, diesel fuel, and others. Individual refineries are typically configured to handle a certain blend of crude oils that will produce an optimized volume of initial and finished products. H = Heavy; M = Medium; L = Light; XL = Extra Light; Sr = Sour; Swt = Sweet; Cond. = condensate.

Definitions: (1) Resid represents residual fuel oil, which is a general classification for heavier oils that can be used as feedstock for a coking refinery; (2) Gas oil refers to fuel oils that are lighter than resid but heavier than distillate and can include certain heating oils and fuels; (3) Distillate can be used as either a diesel fuel or a fuel oil; (4) Naphtha can be blended with other materials to produce motor gasoline or jet fuel. Naphtha can also be used as a solvent or as a petrochemical feedstock; (5) Other generally refers to light refinery gases such as butane and propane.

Oil refiners, which process a blend of different crude oils, generally look to optimize the type/quality of crude streams to produce the desired product (i.e., gasoline and diesel fuel) output based on price (crude oil prices and product values) and other market conditions. The technical configuration, product markets, and economic conditions for each individual refinery will affect the desired crude oil selection.

Prior to the advent of advanced drilling and extraction technologies, many U.S. refiners in the Midwest and Gulf Coast invested in equipment to process heavy crudes from Canada and Latin America. Generally, these investments were encouraged by price discounts for heavy crudes.

¹⁸ Crude oil slate refers to the blend of different crude oils a refinery might process to yield a desired set of petroleum products.

¹⁹ For more information, see Energy Information Administration, “Crude oils have different quality characteristics,” Today In Energy, July 16, 2012.

Tight oil production has changed the situation and the entire industry is adjusting. Investments are being made to process more light crude. Transportation bottlenecks are being relieved. However, as LTO volumes increase, oil producers are bracing for continuing price discounts that may result from a structural oversupply of light crudes in certain regions. Whether the industry will be economically motivated to continue adjusting to accommodate expected light crude production and supply is uncertain.

Legal and Regulatory Context

The export of domestically produced crude oil has been significantly restricted since the 1970s by an array of federal laws and regulations, in particular the Energy Policy and Conservation Act of 1975 (EPCA)²⁰ and the resultant Short Supply Control Regulations adopted and administered by the Bureau of Industry and Security (BIS). These laws and regulations are discussed below.

The Energy Policy and Conservation Act

EPCA directs the President to “promulgate a rule prohibiting the export of crude oil and natural gas produced in the United States, except that the President may ... exempt from such prohibition such crude oil or natural gas exports which he determines to be consistent with the national interest and the purposes of this chapter.”²¹ The act further provides that the exemptions to the prohibition should be “based on the purpose for export, class of seller or purchaser, country of destination, or any other reasonable classification or basis as the President determines to be appropriate and consistent with the national interest and the purposes of this chapter.”²²

This general prohibition on crude oil exports and the exemptions to that prohibition mandated by EPCA are found in the BIS regulations on Short Supply Controls at 15 C.F.R. §754.2. The regulations provide that a license must be obtained for all exports of crude oil, including those to Canada.²³ There are enumerated exceptions to the license requirement for foreign origin crude oil stored in the Strategic Petroleum Reserves,²⁴ small samples exported for analytic and testing purposes,²⁵ and exports of oil transported by pipeline over rights-of-way granted pursuant to Section 203 of the Trans-Alaska Pipeline Authorization Act.²⁶

The regulations provide that BIS will issue licenses for certain crude oil exports that fall under one of the listed exemptions, including (1) exports from Alaska’s Cook Inlet; (2) exports to Canada for consumption or use therein; (3) exports in connection with refining or exchange of Strategic Petroleum Reserve oil; (4) exports of heavy California crude oil up to an average volume not to exceed 25,000 barrels per day; (5) exports that are consistent with certain international agreements; (6) exports that are consistent with findings made by the President under certain statutes (see section below titled “Other Relevant Federal Statutes”); and (7) exports

²⁰ P.L. 94-163.

²¹ 42 U.S.C. §6212(b)(1).

²² *Ibid.* at §6212(b)(2).

²³ 15 C.F.R. §754.2(a).

²⁴ *Ibid.* at §754.2(h).

²⁵ *Ibid.* at §754.2(i).

²⁶ 43 U.S.C. §1652; 15 C.F.R. §754.2(j).

of foreign origin crude oil where, based on satisfactory written documentation, the exporter can demonstrate that the oil is not of U.S. origin and has not been commingled with oil of U.S. origin.²⁷

The regulations also direct BIS to review applications to export crude oil that do not fall under one of these exemptions on a “case by case basis” and to approve such applications on a finding that the proposed export is “consistent with the national interest and the purposes of the Energy Policy and Conservation Act.”²⁸ However, the regulations suggest that only certain specific exports will be authorized pursuant to this case-by-case review. The regulations provide that while BIS “will consider all applications for approval,” generally BIS will only approve those applications that are either for temporary exports (e.g., a pipeline that crosses an international border before returning to the United States), or are for transactions (1) that result directly in importation of an equal or greater quantity and quality of crude oil; (2) that take place under contracts that can be terminated if petroleum supplies of the United States are threatened; and (3) for which the applicant can demonstrate that for compelling economic or technological reasons, the crude oil cannot reasonably be marketed in the United States²⁹

The Export Administration Act and the International Emergency Economic Powers Act

Although EPCA directs the President to promulgate regulations that restrict crude oil exports, it does not provide the regulatory framework for enforcement of that restriction and the issuance of licenses for eligible exports. As mentioned above, the BIS is tasked with that duty, which is handled under its “short supply control” regulations. The source of this authority is somewhat complicated. The Export Administration Act of 1979 (EAA)³⁰ confers upon the President the power to control exports for national security, foreign policy, or short-supply purposes, authorizes the President to establish export licensing mechanisms for certain items, and provides guidance and places certain limits on that authority.³¹ These restrictions are enforced by BIS. Crude oil restrictions and licensing are found in the BIS short supply controls authorized by the EAA.

However, the EAA expired in August 2001. The provisions of the act, and the regulations issued pursuant to it, remain in effect via yearly executive orders issued by the President under authority granted to him by the International Emergency Economic Powers Act.³² That act authorizes the President to “deal with any unusual and extraordinary threat, which has its source in whole or substantial part outside the United States, to the national security, foreign policy, or economy of the United States, if the President declares a national emergency with respect to such threat.”³³

²⁷ 15 C.F.R. §754.2(b)(1). For example, Canadian crude oil transported to the U.S. Gulf Coast via the controversial Keystone XL Pipeline, if it met the commingling requirement, would be eligible for export. For additional background and analysis of the Keystone XL Pipeline, see CRS Report R41668, *Keystone XL Pipeline Project: Key Issues*, by Paul W. Parfomak et al.

²⁸ Ibid. at §754.2(b)(2).

²⁹ Ibid.

³⁰ P.L. 96-72.

³¹ For additional analysis of the EAA and federal export controls, see CRS Report R41916, *The U.S. Export Control System and the President’s Reform Initiative*, by Ian F. Fergusson and Paul K. Kerr.

³² P.L. 95-223.

³³ 50 U.S.C. §1701(a).

When the EAA first expired in 2001, the President cited this emergency authority in the issuance of Executive Order 13222, which provided for the continued execution of the EAA and the regulations issued pursuant to it.³⁴ This exercise of emergency authority has been repeated annually by the President since that time, most recently in August 2013.³⁵

Other Relevant Federal Statutes

In addition to the statutes described above, several other federal statutes either bar certain types of crude oil exports or mandate that certain crude oil exports be exempt from the general prohibition in EPCA.

Section 201 of P.L. 104-58: Exports of Alaskan North Slope Oil

Section 201 of P.L. 104-58 amended the Mineral Leasing Act (MLA),³⁶ to authorize the export of oil transported by pipeline over the right-of-way granted pursuant to the Trans-Alaska Pipeline Authorization Act unless the President finds that export of this oil is not in the national interest.³⁷ The President's national interest determination must, at a minimum, consider (1) whether the export will diminish the quantity or quality of petroleum available in the United States; (2) the results of an environmental review; and (3) whether the export might cause sustained material oil supply shortages or significantly increase oil prices above world market levels.³⁸ The legislation required submission of this national interest determination within five months of November 28, 1995.³⁹

In April 1996, President Clinton issued a determination that such exports were in the national interest.⁴⁰ BIS administers authorizations of Trans-Alaska Pipeline System oil exports pursuant to 15 C.F.R. §754.2(j), which carves out an exception to the general crude oil export licensing requirements provided that certain conditions regarding the physical transportation of the crude oil are satisfied.

MLA Limitation on Export of Crude Oil Transported via Federal Right-of-Way

Section 28(u) of the MLA clarifies that all domestically produced crude oil (except oil exchanged for similar quantities for purposes of convenience or efficiency) transported through federal lands via rights-of-way granted pursuant to the MLA “shall be subject to all of the limitations and licensing requirements of the Export Administration Act.”⁴¹ Section 28(u) also provides that before such exports may occur, the President must “make and publish an express finding that such exports will not diminish the total quantity or quality of petroleum available in the United

⁴⁰ Memoranda of President: Exports of Alaskan North Slope (ANS) Crude Oil, 61 Fed. Reg. 19,507 (May 2, 1996).

⁴¹ 30 U.S.C. §185(u).

States, and are in the national interest and are in accord with the provisions of the Export Administration Act.”⁴² The MLA further directs the President to submit reports to Congress containing these findings, and provides that Congress “shall have a period of sixty days, thirty days of which Congress must have been in session, to consider whether exports under the terms of this section are in the national interest. If Congress ... passes a concurrent resolution of disapproval stating disagreement with the President’s finding concerning the national interest, further exports ... shall cease.”⁴³ The MLA restriction on exports of crude oil that are transported through federal lands via a right-of-way is incorporated into the BIS regulations at 15 C.F.R. §754.2(c)(ii).

Limitation on Export of Oil from the Naval Petroleum Reserves

10 U.S.C. §7430(e) provides that petroleum produced at the naval petroleum reserves (except petroleum exchanged for similar quantities for purposes of convenience or efficiency) “shall be subject to all of the limitations and licensing requirements of the Export Administration Act.” Section 7430(e) also provides that before such exports can take place, the President must “make and publish an express finding that such exports will not diminish the total quantity or quality of petroleum available in the United States, and are in the national interest and are in accord with the provisions of the Export Administration Act.”⁴⁴ The Section 7430(e) restriction on exports of petroleum produced at the naval petroleum reserves is incorporated into the BIS regulations at 15 C.F.R. §754.2(c)(iv).

Limitation on Export of Crude Oil Produced from the Outer Continental Shelf

Section 28 of the Outer Continental Shelf Lands Act (OCSLA)⁴⁵ provides that any oil or gas produced from the Outer Continental Shelf (OCS)⁴⁶ “shall be subject to all of the limitations and licensing requirements of the Export Administration Act.” As with the statutory export limitations discussed above, exports meeting this description are only authorized if the President makes “an express finding that such exports will not increase reliance on imported oil or gas, are in the national interest, and are in accord with the provisions of the Export Administration Act.”⁴⁷ The OCSLA requires the President to submit reports containing such findings to Congress and provides that Congress “shall have a period of sixty calendar days, thirty days of which Congress must have been in session, to consider whether exports under the terms of this section are in the national interest. If the Congress ... passes a concurrent resolution of disapproval stating disagreement with the President’s finding concerning the national interest, further exports ... shall cease.”⁴⁸ The OCSLA restriction on exports of petroleum produced from the OCS is incorporated into the BIS regulations at 15 C.F.R. §754.2(c)(iii).

⁴⁷ 43 U.S.C. §1354(b).

⁴⁸ Ibid. at §1354(c). Note that similar legislative veto provisions elsewhere in the U.S. Code were declared unconstitutional in *INS v. Chadha*, 462 U.S. 919 (1983).

The Role of the Bureau of Industry and Security (BIS)

As noted above, exports of crude oil are licensed under the short supply controls of the Export Administration Act. The Export Administration Regulations (EAR) codify the requirements and provisions of the various statutes, which are administered by the Bureau of Industry and Security. Except in certain instances, a license is required for the export of crude oil from the United States.

License applications are examined by the Office of National Security and Technology Transfer Controls at BIS. Only a U.S. exporter or entity may apply for a license. License applications are made electronically, thus one must register on the BIS Simplified Network Application Process Redesign (SNAP-R).⁴⁹ Once registered, the applicant must list the exporter, consignee, the volume of the export and its monetary value, a description of the product, its end-use, and a certification of origin for the product.

All BIS license applications are handled according to Executive Order 12981. Within nine days, BIS must contact the applicant if additional information is required; return without action if additional information is required or if a license is not needed; or refer the application to another agency. Once an application has been submitted, BIS has 30 days to make a decision. However, unlike dual-use technology licenses, crude oil licenses are not referred to other agencies. Thus, most crude oil licenses are handled within a 7-10 day period. A license is good for one year and is non-transferable, unless it is part of the assets of a company being bought or sold.

Certain crude oil exports can be shipped with a license exception. A license exception is an authorization to export or re-export, under certain conditions, items subject to the EAR that normally would require a license. Basically, under a license exception, the exporter certifies that a lawful transaction is taking place while maintaining proper documentation. The three license exceptions available for crude oil exports are (1) shipments of foreign-origin crude stored in the Strategic Petroleum Reserve; (2) shipments of samples for analytic or testing purposes; and (3) Trans-Alaska pipeline shipments. In order to use the TAPS license exception, certain tanker routing and environmental restrictions must be observed. Additionally, vessels used to export TAPS crude oil must be U.S.-owned and crewed. In addition, the licenses allow no re-exports, thus, prohibiting, for example, trans-shipments to foreign destinations through Canada.

The number of crude oil license applications has steadily increased over the last few years, from 31 applications in FY2008 to 103 in FY2013 (see **Table A-1** in **Appendix A** for additional detail). In the last several years, no licenses have been rejected, although some have been returned without action. This high approval rate is likely due to the specificity and exporters' knowledge of the regulations. The vast majority of licenses are for exports to Canada. For countries other than Canada, the exports can be attributed to re-exports of foreign crude oil that has not been commingled with domestic crude.

Crude Oil Export Motivations

As tight oil production has rapidly increased, technical and economic factors are motivating some stakeholders to pursue lifting crude oil export restrictions. Some oil producers would like to

⁴⁹ For more information about SNAP-R, see <https://www.bis.doc.gov/index.php/licensing/simplified-network-application-process-redesign-snap-r>.

receive higher prices for oil produced. However, some refiners are concerned that regional crude oil acquisition price discounts may narrow if exports are expanded. Narrow price discounts may affect refinery operating margins and may result in some refineries ceasing operations. Additionally, some refiners may need to consider capital investments necessary to absorb increasing volumes of LTO—along with the value of products yielded from refining LTO. As mentioned above, the geographic location of tight oil production, refinery configurations, infrastructure limitations, and prices received by some oil producers have been cited as justification for lifting export restrictions. However, it is important to realize that these factors are not static in nature. Rather, they are dynamic and are constantly changing. Refineries can adjust their operations. Transportation infrastructure can adjust based on market conditions. Therefore, oil values received by oil producers would likely adjust as well. In 2013, the Energy Information Administration stated:

Some recent commentary has suggested that it was likely or even inevitable that the growth in U.S. oil production from tight resources would be significantly curtailed unless there was a relaxation of current U.S. policies toward crude oil exports. However, this is likely an overstatement of the actual situation, because there are several other midstream and downstream adjustments that could help to accommodate changing production patterns.⁵⁰

The dynamic nature of the oil industry makes the debate about oil export policy inherently complex. Each of the three primary industry segments—production, transportation, and refining—will adjust based on changes to any one of the other segments. As a result, it can be difficult to assess the potential impacts of policy decisions on any one segment without considering how the other two might adjust to changing market conditions. With that caveat, additional detail about some of the motivations for crude oil exports is provided in the following sections.

Tight Oil Production Has Increased

In 2000, approximately 250,000 bbl/d of tight oil was produced in the United States.⁵¹ In 2012, U.S. tight oil production was 2.25 million bbl/day, a nearly 10-fold increase.⁵² The Energy Information Administration (EIA) 2014 reference case projects that U.S. tight oil production will continue to increase in the near to medium term and projects that LTO production may peak at 4.8 million bbl/day in 2019.⁵³ Most of this production is expected to come from three tight oil formations: (1) Eagle Ford in Texas, (2) Permian Basin in Texas, and (3) Bakken in North Dakota (see **Figure 2**). It is important to note that EIA projections for LTO production are subject to assumptions that are based on currently available information and current policies (e.g., export restrictions). These projections would likely change over time as new information becomes available and if policies are modified. Some degree of uncertainty exists in terms of how much LTO might be produced. Future projections may be either higher or lower than those included in EIA's 2014 Annual Energy Outlook.

⁵⁰ Energy Information Administration, "Absorbing Increases in U.S. Crude Oil Production," *This Week in Petroleum*, May 1, 2013.

⁵¹ EIA 2014 AEO.

⁵² *Ibid.*

⁵³ *Ibid.*

Timing for a potential oversupply, and resulting price discounts, of U.S. LTO is also uncertain and depends on several factors. Some analysts estimate that price discounts related to the combination of LTO production volumes and export restrictions may occur as early as 2015/2016 or sometime after 2020.⁵⁴ Some of the factors that will likely impact the timing and magnitude of price discounts include (1) actual LTO production levels, (2) potential for U.S. exports to Canada, (3) LTO access to West Coast markets, (4) potential to displace light sour and medium grade crudes in refineries, and (5) the amount of additional LTO processing capacity at refineries.⁵⁵

Figure 2. U.S. Tight Oil Production, by Formation
(2000-2040 Reference Case est.)

Source: Energy Information Administration, Annual Energy Outlook 2014 Early Release. High Resource/Improved Technology Case preliminary projections were provided by EIA and are used with permission.

Notes: The area chart shows EIA’s reference case projections for tight oil production by formation. The red dashed line shows EIA’s high resource/improved technology case for total tight oil production out to 2040. The disparity between these two projections illustrates some of the uncertainty associated with long-term tight oil production in the United States. Locations for tight oil formations are as follows: Bakken, North Dakota; Eagle Ford, Texas; Permian, Texas and New Mexico; Woodford, Oklahoma; Austin Chalk, Texas, Louisiana, and Mississippi; Niobrara, Colorado and Wyoming; Monterey, California.

Based on EIA reference case projections in **Figure 2**, LTO production is projected to rapidly increase and peak around 2019. The implication of the reference case production profile is that the window of opportunity for crude oil exports—depending on export volumes—may be temporary. The potential temporary nature of the export opportunity may reflect the continuous

⁵⁴ Turner, Mason & Company, “U.S. Crude Export Restrictions: Industry Responses and Impacts,” February 28, 2014.

⁵⁵ Ibid.

and rapid drilling that may be needed to maintain and increase LTO volumes. Although, EIA's preliminary High Resource case indicates that LTO may continue growing out to 2040. As noted above, actual and projected production can, and does, change over time. The High Resource case reflects how industry knowledge could expand and technologies could improve, thereby resulting in increased U.S. LTO production in the future. LTO production at scale is a relatively new industry development and, thus, it is likely too early to accurately predict the magnitude of future production levels.

One element of LTO production is the increase in extremely light hydrocarbons that might be classified as lease condensate, which is subject to export restrictions. While there is no quality characteristic (i.e., API gravity) that defines lease condensate, increasing production volumes of condensate and condensate-like material is one aspect of the crude oil export debate. For additional information, see the text box below.

Lease Condensate: What is it? Is it Crude Oil?

Production of lease condensate, especially in the Eagle Ford formation in Texas, has emerged as a topic of debate in the context of U.S. crude oil exports. As the name implies, condensate is generally a gas underground. When it is produced along with oil and gas, it "condenses" into a liquid at atmospheric temperature and pressure. According to one source, the majority of Eagle Ford condensate is being produced from natural gas wells, not crude oil wells.⁵⁶ While "lease condensate" is included in the BIS crude oil definition, there is a potential contradiction within the definition. BIS defines crude oil as hydrocarbons that existed in liquid phase underground. However, condensate is generally in a gas phase underground and condenses to a liquid at atmospheric conditions. This apparent contradiction, along with other considerations, raises questions about the applicability of export restrictions to condensate.

As a point of comparison, the Energy Information Administration defines condensate as follows:

Condensate (lease condensate): Light liquid hydrocarbons recovered from lease separators or field facilities at associated and non-associated natural gas wells. Mostly pentanes [hydrocarbons with five carbon atoms] and heavier hydrocarbons. Normally enters the crude oil stream after production.⁵⁷

There does not appear to be a standard quality characteristic—such as API gravity—used to classify what is and is not lease condensate. Additionally, there is limited information available that quantifies actual and expected volumes of condensate produced on an annual basis, because lease condensate is typically classified as crude oil for reporting purposes. As a result, it can be difficult to accurately assess condensate production volumes when considering policy options that might allow this material to be exported. According to one estimate, lease condensate production in 2013 was approximately 1 million bbl/d and may reach 1.6 million bbl/d by 2018.⁵⁸

Furthermore, the EIA definition of condensate is very similar to the definition of "natural gasoline," which is defined as being "equivalent to pentanes plus."⁵⁹ Natural gasoline is a product of gas processing facilities. Some market analysts have indicated that depending on the season—winter or summer—identical hydrocarbons can be classified as either natural gasoline, which can be exported without restriction, or condensate, which is subject to export restrictions.⁶⁰

Additionally, the BIS crude oil definition states that crude oil hydrocarbons that have not passed through a distillation tower are subject to export restrictions. In order to comply with the regulation, investments are being made to install stand-alone condensate splitters—essentially a basic distillation tower—that separate the components (e.g., naphtha) of condensate. The resulting condensate components are eligible for export to international markets. As a result of the above considerations, some industry stakeholders have called for condensate to be removed from the BIS definition.

Actual and projected LTO production levels are affecting the refining and infrastructure segments in a variety of ways, and vice versa. How these segments might adjust to changing market conditions (i.e., increased LTO production) will depend on multiple economic variables and investment considerations.

U.S. Refinery Configurations⁶¹

As of October 2013, there were 115 oil refineries in the United States with a total operable capacity of 17.8 million barrels per day of crude oil throughput.⁶² Each refinery has its own unique configuration that is generally designed to economically optimize the use of a certain crude oil blend and the production of oil products that will maximize profit margins. In the context of exporting crude oil, refineries located in the Petroleum Administration for Defense District (PADD) 3 provide an illustration of some of the emerging complexities and economic decisions that are being considered as LTO production increases in the Gulf Coast area, and as Canadian and Midwest crudes are delivered to the region.⁶³

There are 43 refineries located in PADD 3, with a total operable refining capacity of approximately 9.1 million barrels per day, the largest concentration of refining capacity in the country.⁶⁴ Nearly half of the refineries in PADD 3 are equipped with coking units (**Figure 3**), a refinery process that upgrades heavy residual material from a refinery's distillation unit and converts this material into higher-value products such as naphtha and distillate.⁶⁵ Adding a coking unit to a refinery is an expensive endeavor, with estimated costs in the \$1 billion+ range. Generally, the decision to add coking capacity to a refinery is based on an expectation that the refinery will be able to purchase heavier crude oils that generally sell at a discount, and can yield certain oil products that are highly valued in domestic and international markets. Approximately 60% of PADD 3 refiners are considered coking refineries (**Figure 3**). Investments in coking capacity were made based on an expectation that price-discounted heavy crudes from Canada and Latin America would be increasingly available.

Figure 3. Oil Refining Capacity and Coking Refinery Capacity by PADD

Source: Energy Information Administration, CRS.

Notes: Numbers may not sum due to rounding. PADD 2 tight oil production is for Bakken only. PADD 3 tight oil production reflects actual and expected crude oil production in both the Eagle Ford and Permian Basin formations. Tight oil production numbers are from EIA's 2014 Annual Energy Outlook reference case scenario.

Increased production—both actual and forecasted—of LTO in PADD 3, primarily from the Eagle Ford and Permian Basin tight oil formations, may cause some refiners in this region to assess their optimal economic operating parameters. Each individual refiner will likely evaluate economic conditions—crude oil prices and product values—to determine if processing additional volumes of LTO is economically justified. While it may be challenging for PADD 3 refiners to process increasing volumes of LTO based on a refinery's current configuration, investments can be made to handle additional volumes of LTO. However, LTO price discounts, product values and volume commitments, investment requirements, and economic optimization for each individual refiner will dictate the additional volume of LTO that is ultimately absorbed. Whether such investments might actually be made is beyond the scope of this report.

In addition to making investments in refining equipment, reducing import volumes of light sweet crude into PADD 3 is one possible avenue for absorbing more domestically produced LTO, but some refiners may have already exhausted this option. Indications are that light sweet crude imports are approaching extremely low levels and there may be limited opportunities to further reduce light sweet imports—based on current refinery configurations—if U.S. LTO production continues to increase as projected. As an example, PADD 3 light sweet imports from Nigeria were at or near zero at the end of 2013 (Figure 4).

Figure 4. PADD 3 Light, Sweet Crude Oil Imports from Nigeria
2008-2013

Source: CRS using data from the Energy Information Administration. See EIA website, *Petroleum & Other Liquids: Imports/Exports & Movements*, <http://www.eia.gov/petroleum/data.cfm#imports>, accessed January 28, 2014.

Additionally, some estimates project that total North American light crude oil imports may go to zero by the end of 2014.⁶⁶ Once total light crude imports are reduced to zero, refiners may begin evaluating options to reduce medium- and heavy-quality crude imports. However, foreign oil suppliers—notably Saudi Arabia and Venezuela—have ownership positions in some U.S. refinery assets. These countries could choose to continue providing oil, in some cases at discounts compared to available U.S. crudes, to their U.S. refineries in order to maintain presence in the U.S. oil market. Should countries elect this option, there may be limits to reducing crude oil imports. The ability of refiners to utilize more LTO is one consideration. However, transporting crude oil from production fields to refiners is another issue that can impact LTO price discounts and refining economics.

Infrastructure Challenges

One consideration for U.S. oil producers is the availability and cost of transportation infrastructure to deliver crude oil to refineries. Delivery infrastructure, and the cost associated with various transportation modes, can affect the value of oil that is produced in certain locations. LTO production growth in certain parts of the country is resulting in some constraints associated with moving crude oil to refiners.⁶⁷

⁶⁶ Raymond James Energy Group, “Still Bearish on Oil & Gas Prices But There is Light at the End of the Tunnel,” February 12, 2014.

⁶⁷ For additional background about U.S. oil transportation infrastructure, see Energy Policy Research Foundation, *Pipelines, Trains, and Trucks: Moving Rising North American Oil Production to Market*, October, 21, 2013.

Crude oil is transported via pipeline, rail, marine vessel, and truck. Pipelines are the primary means of crude oil transportation in the United States. Generally, the U.S. crude oil pipeline network was originally designed to move crude oil and petroleum products generally northward from the Gulf Coast to Cushing, Oklahoma, and other destinations (See **Figure 5**). The geographic distribution of LTO production—currently concentrated in North Dakota and Texas—is constraining the existing U.S. pipeline delivery system, thereby creating market access challenges for some oil producers.

Figure 5. Major U.S. and Canadian Crude Oil Pipelines

Source: CRS using data from Platts Quarter 4, 2013 dataset. Map created on February 6, 2014.

Notes: The figure above is a simplified illustration of the U.S. crude oil pipeline network. Many small and short distance pipelines are not included.

To address these challenges, the crude oil transportation network is evolving: (1) some pipelines are reversing oil flow direction,⁶⁸ (2) new pipelines are being developed,⁶⁹ (3) rail shipments are increasing to deliver LTO from North Dakota to the east and west coasts, as well as the Gulf Coast,⁷⁰ and (4) LTO waterborne shipments are also increasing. Waterborne shipments must

⁶⁸ One pipeline reversal example is the Seaway pipeline (between Cushing, OK and the Freeport, Texas area) reversal and expansion project. For more information see, Oil Daily, “Seaway Expansion Now Slated for Late Second Quarter,” January 31, 2014.

⁶⁹ For example, Enbridge is in the process of developing the Sandpiper Project; a new pipeline that would transport Bakken crude oil from North Dakota to Wisconsin. For more information, see <http://www.enbridge.com/SandpiperProject>.

⁷⁰ For additional analysis, see CRS Report R43390, *U.S. Rail Transportation of Crude Oil: Background and Issues for Congress*, by John Frittelli et al.

comply with Jones Act requirements.⁷¹ Transportation costs and constraints contribute to different oil values at various delivery points throughout the country. While infrastructure adjustments are occurring, it is unclear how much LTO volume these adjustments will ultimately accommodate. Depending on their location and the cost of transportation modes available, some oil producers may argue that allowing crude oil to be exported would serve to equalize prices by alleviating some of the infrastructure-related price discounts in the market. Infrastructure limitations and resulting price discounts will impact the volumes of oil produced as well as refiner decisions to utilize incremental LTO production.

Crude Oil Producer Prices

Ultimately, the objective of U.S. oil producers is to maximize the value, or selling price, of each barrel of oil produced. U.S. oil producers throughout the country receive different prices, which can be affected by oversupply in a certain region due to production levels, refinery demand, and/or infrastructure limitations. **Figure B-1 in Appendix B** provides price history information for selected crude oil types. Allowing crude oil to be freely exported may have the result, all other things being equal, of reducing producer price discounts in some parts of the country, thereby equalizing the value of LTO to match global crude prices, adjusted for quality and yield characteristics and the cost of transportation. However, allowing crude oil prices to normalize may negatively impact certain refiners that are currently profitable due, in part, to regional crude oil price discounts.

For example, spot prices for Bakken LTO have experienced price discounts compared to the U.S. West Texas Intermediate (WTI) benchmark. EIA reports that Bakken discounts have been as high as \$28 per barrel, but have since adjusted—a result of changes to the oil transportation network (see “Infrastructure Challenges” section above)—to lower levels as logistic constraints have been alleviated in the region.⁷² Eagle Ford LTO in Texas has not experienced significant price discounts like those observed in the Bakken, likely due to its relatively closer proximity to refining customers and fewer transportation challenges. Eagle Ford condensate prices are more difficult to assess (see “Condensate” text box above). While official price information does not include a condensate category, some refiners do post prices for various crude types, including condensate. A February 2014 price bulletin shows an Eagle Ford condensate price discount of \$6.50 per barrel, compared to Eagle Ford crude oil.⁷³ This discount suggests that condensate may be a less desirable feedstock for certain refineries.

As LTO production increases, transportation bottlenecks and limited refinery demand for LTO and condensate feedstock may put downward pressure on LTO producer prices. While refining and transportation adjustments will likely occur, lower prices may result in less oil production, depending on the severity of the price discount and the economics of specific oil production

⁷¹ The Jones Act requires that vessels transporting cargo between two U.S. points be built in the United States, as well as crewed and at least 75% owned by U.S. citizens. For information about the growth in waterborne shipments, see Platts Oilgram Price Report, “US Jones Act fleet strains to meet demand,” February 18, 2014.

⁷² Energy Information Administration, “Bakken crude oil price differential to WTI narrows over last 14 months,” *Today in Energy*, March 19, 2013.

⁷³ Flint Hills Resources (FHR) publishes price bulletins for various crude oil types. The \$6.50 price difference mentioned above was derived from the FHR February 21, 2014 price bulletin by subtracting the difference between “Eagle Ford, crude oil less than 50 API” and “Eagle Ford Condensate, equal to or greater than 60 API.” FHR price bulletins are available at, <http://www.fhr.com/refining/bulletins.aspx>.

projects. Furthermore, the relationship between producer prices and refinery acquisition costs is dynamic. As transportation networks and refinery configurations adjust to a changing crude oil slate, prices should reflect bottlenecks and limitations that exist. Under constraint conditions, the price discounts needed to motivate system modifications, in combination with price levels needed to incentivize incremental oil production, are uncertain and can be difficult to estimate due to the integrated and dynamic nature of production, transportation, and refining. Such estimates are beyond the scope of this report.

Considerations for Congress

Debate about U.S. crude oil exports is complex, dynamic, multidimensional, and includes many different stakeholder views. As a result, there are several issues that Congress may consider during future debate about crude oil exports. The following sections discuss some of these considerations.

Price Effects

According to the economic theory of international trade, opening markets to world trade tends to push the domestic price of the traded good toward the world price. Additionally, if the volume of products entering the world market is sufficiently large, the world price may also adjust to account for the new world supplies. Although the U.S. oil market has been open to world trade for many years, it has generally been in one direction. While large volumes of imported crude oil have helped to provide for the consumption of petroleum products, exports of crude oil have essentially been prohibited. The price of oil is determined on the world market, and any changes in demand and/or supply which might be expected to affect the price of oil must be set against world levels of market activity. As the United States considers whether to allow the export of domestic crude oil to the world market, price changes are likely to occur consistent with those suggested by international trade theory.

Crude Oil Prices

The price effects of allowing the export of crude oil from the United States to the world market are likely to be threefold. First, the domestic price of LTO, or other grades of exported oil, is likely to converge toward the world price. Second, the price of the U.S. reference crude grade—West Texas Intermediate (WTI)—is likely to adjust relative to world reference grade crude oils, notably Brent.⁷⁴ Third, the world price of oil is likely to adjust to reflect added U.S. supplies to the world total, all else being equal. See **Figure B-1** in **Appendix B** for price history information for selected crude oil types.

The actual magnitude of these price effects will be determined by the volume of crude exports from the United States that actually materialize. For example, should U.S. exports of LTO settle at about 500,000 barrels per day,⁷⁵ this would represent nearly one half of the total output from

⁷⁴ Brent crude oil is produced from the North Sea with similar qualities to WTI. It is generally used a benchmark for world oil prices.

⁷⁵ The export volume level of 500,000 bbl/d is used as an example only and was selected based on witness testimony and analyst presentations that suggest an oversupply of 500,000 bbl/d of condensate and light sweet crude oil in the (continued...)

the Bakken field in 2013, 2.5% of total U.S. consumption, and 0.5% of world demand for oil.⁷⁶ As a result, the observed price effects on Bakken, and other price-discounted domestic crude oils might be expected to be relatively large, while the effects on U.S. reference prices and the world price of oil might well be smaller.

Shale based LTO, since its entry to the U.S. market, has sold at a discounted price relative to other domestic crude oils of similar quality. As described in this report, the location of the oil, the lack of infrastructure to move the oil to refineries, and the technological characteristics of U.S. refineries all contributed to the need of suppliers to discount the price to induce refiners to purchase available supplies. The EIA reported that since 2012 the price of Bakken crude oil has been discounted by as much as \$28 per barrel compared to WTI.⁷⁷ While price discounts were less during most of the years 2012-2013, discounts were necessary to help cover the added cost of rail shipment of Bakken crude oil, which averages \$10 to \$15 per barrel nationwide. Rail shipment costs are as much as three times the cost of shipping oil by pipeline.⁷⁸

Allowing the export of LTO would likely create additional demand for these crude oils that could cause the price to rise from discounted levels in the U.S. market to approach those earned by other light, sweet crudes in the world market. This would have the effect of reducing or eliminating the discount experienced in the U.S. market. Transportation infrastructure limitations would likely limit the quantities of exportable oil and add to its cost, but the potentially higher price earned by producers could help expand the industry. Investment in the fields might increase and with it oil production and related job creation.

Introduction of LTO exports might also affect the price spread between WTI and Brent crudes. This could happen as the result of two price effects. First, as domestic LTO becomes relatively less available on the domestic market, reflecting the quantities entering the world market, the price of WTI is likely to rise as the domestic market tightens. Second, the price of Brent has been especially high since the Libyan revolution, which led to reduced supplies of light, sweet crude oil to Europe. While the direction of change in both prices may be estimated based on market theory, the actual magnitude of the price change would likely depend on the quantity of U.S. crude oil exported. A reduction in the WTI-Brent price spread as a result of these factors would be favorable for oil production and producers in the United States, with somewhat higher product prices for some U.S. consumers. A reduction in the price of Brent would primarily benefit European consumers, although the benefits of lower prices could extend to the world market.

An increase in supply of LTO to the world market of, for example, 500,000 barrels per day, or 0.5% of world demand, would not be expected to have a large effect on world oil prices. A qualification to this observation is that the elasticities of both demand and supply in the world market are very low. As a result, changes in the quantities demanded or supplied on the market can have exaggerated effects on price. Among the effects of U.S. exports might be a reduced call

(...continued)

2015 to 2016 timeframe. ⁷⁶ Export volumes will be determined by market forces and decisions by firms producing crude oil.

⁷⁷ Energy Information Administration, Today in Energy, March 19, 2013.

⁷⁸ Energy Information Administration, Today in Energy, July 26, 2012.

on Organization of the Petroleum Exporting Countries (OPEC) crude oil and an increase in effective spare oil production capacity in the world market.

OPEC provides crude oil to fill the gap between world demand and the total production from all other, non-OPEC, oil producers. Nations tend to use domestic crude oil and the supplies available from close exporters before calling on OPEC producers for supply. If the call on OPEC producers is reduced, this amounts to an increase in spare capacity in the sense that supplies, if withdrawn from the market, could re-enter the market in the event of an unanticipated demand increase or a supply emergency. An increase in spare capacity might be expected to reduce the potential for price volatility in the oil market. The escalating prices of the summer of 2008 were associated with a period of high demand that strained available supply, which caused excess capacity to fall to low levels.

Product Prices

Changes in the prices of petroleum products directly affect consumer costs and behavior at the pump. According to EIA, 68% of the consumer's cost of gasoline and 57% of the consumer's cost of diesel fuel is directly attributable to the refiner's cost of crude oil. Therefore, changes in the price of crude oil are likely to result in proportional changes in the prices of petroleum products. This implies that the crude oil price effects analyzed in the previous section of this report will directly affect U.S. consumers.

The observed price discounts on Bakken crude largely, but not entirely, accrued to refiners supplying the Midwest and Rocky Mountain regions. A result of the availability of discounted crude oil may be that gasoline and other petroleum product prices were lower in those regions, compared to the national average. For example, during the period January 2012 through January 2014 Midwest gasoline prices were lower than national average gasoline prices during 21 of 24 months. As the price of local crude oil supplies rises to reflect convergence with the world price of oil, the benefit of these lower prices to regional consumers is likely to be reduced.

If world oil prices decline as a result of U.S. exports, this could result in somewhat lower petroleum product prices for U.S. consumers as refiners use a mixture of domestic and imported crude oils that are tied to the world price of oil. This could occur if the quantity weighted reduction in world prices more than offset the quantity weighted increase in regional domestic prices. Although a fall in world oil prices might be predicted, its magnitude may be small should the amount of U.S. crude oil exports be small relative to the world market.

By contributing to an increase in world spare capacity, U.S. exports could contribute to less volatile prices in the world oil market. Price stability, coming from less reaction to the numerous supply problems that plague the supply side of the market, could reduce market uncertainty, possibly bringing benefits to national and international energy planners.

Energy Security and Geopolitics

Although there has been some debate over U.S. crude oil exports, the effects of rising U.S. oil production have already been felt in international markets and on geopolitics. While increased oil production has allowed the United States to alter its geopolitical posture, the U.S. government has not used its oil production as leverage over other countries, and has been critical of countries that

do.⁷⁹ Furthermore, the U.S. government does not directly control either oil production or the companies that do produce oil.

The rise in U.S. production has decreased the need for imports, improving the U.S. trade balance, and leaving more oil and spare production capacity on the world market. It has also contributed to an increase in refined petroleum product exports, an activity not prohibited by U.S. law. The change in perspective of the United States being a major oil importer to possibly an exporter has altered the United States' place in world energy. Countries that viewed the United States as a declining economic power now view it as having competitive advantages in new sectors related to petroleum. Some oil producing countries that viewed the United States as a market destination may now view it as a competitor.

If the United States changes its import/export position and potentially its rules regarding crude exports, the effects on geopolitics will differ depending upon how and when the changes occur in addition to the expected volume of exports. In the short term, as has already been raised, the United States may consider allowing more exports of crude oil to correct a possible market inefficiency due to refining capacity and crude oil specifications. In the medium term, whether U.S. laws will be changed to allow greater export of crude oil remains a key question. In the long term, if U.S. laws and regulations were changed to promote crude oil exports, how big of an exporter would the United States become remains the central question to the impact on geopolitics.

The U.S. posture towards sanctions against Iran, including by some Members of Congress, has become more stringent, in part because of the rise in U.S. oil production.⁸⁰ Additionally, the decline in U.S. imports has made the United States less reliant on certain OPEC countries, primarily Nigeria (see **Figure 4**).⁸¹ OPEC, at least publicly, has “welcomed” the rise in U.S. oil production as stabilizing to the market.⁸² Saudi Arabia, the world's largest crude oil exporter, has also indicated support for increased U.S. oil production as well as exports.⁸³ However, some analysts argue that the United States is shifting its interest (i.e., military presence) from key oil producing regions, like the Middle East, because of its newfound resources.⁸⁴ Additionally, other industry analysts speculate that Saudi Arabia may discount its crude oil and refined product exports to the United States in order to stay in the U.S. market for strategic reasons.

⁷⁹ Prior to the 1973 Arab oil embargo, world oil markets were controlled by U.S. and European companies. U.S. production played a swing role in matching supply and demand, and the Texas Railroad Commission dominated U.S. production. Concern with “energy security” is related to the reaction in the United States to the “oil shocks” of the 1970s when Americans first realized that the cost, and even availability, of gasoline could be interrupted for political reasons. Since the 1970s Presidents have sought, to one degree or another, to isolate the nation from the politics of world oil markets, to little effect.

⁸⁰ S. 965 was introduced in the first session of the 113th Congress calling for the expansion of U.S. oil production to displace all of Iran's exports on the world market.

⁸¹ Nigerian imports to the United States are mainly light, sweet crude, which the United States is producing more of.

⁸³ Briefing by Saudi Arabia's Minister of Petroleum and Mineral Resources, Ali bin Ibrahim Al-Naimi, to congressional staff delegation, January 21, 2014.

⁸⁴ John Kemp, “America's energy revolution transforms international relations,” *Reuters*, January 28, 2014, pp. <http://in.reuters.com/article/2014/01/28/energy-diplomacy-idINL5N0L22YK20140128>.

U.S. consumption of petroleum products was 18.49 million barrels per day in 2012 compared to the peak rate of 20.80 million barrels per day in 2005. In 2012, the United States produced 6.49 million barrels per day of crude oil and imported 8.53 million barrels per day with the difference between consumption and production plus imports being made up of non-crude oil inputs (i.e., natural gas liquids, biofuels, refinery gain) to the refining system. In 2005, the United States produced 5.18 million bbl/d and imported 10.13 million bbl/d. Over two-thirds of imports came from Canada, Saudi Arabia, Mexico, and Venezuela in 2012 and almost 60% in 2005.⁸⁵

Canada and Mexico are considered to be reliable suppliers. Saudi Arabia and Venezuela, both OPEC members, own extensive refining assets in the United States (Motiva and Citgo refineries respectively) and as a result might be expected to desire to maintain a presence in U.S. oil markets. Beyond these 4 countries, over 30 other countries supply the United States with crude oil, none at levels expected to be difficult to replace if emergency conditions might develop.

Should the United States remove barriers to crude oil exports, the amount of exports may not matter as much as the psychological impact. The view that the United States is committed to the global energy market may have the greatest effect. Even in the long run, most industry analysts do not project that the United States will produce more crude oil than it consumes (see **Figure 1**). Nevertheless, any additional barrels that the United States produces will dilute OPEC's market share, assuming demand stays the same, and this may be viewed positively by most oil consuming countries.⁸⁶

U.S. oil production is rising and is projected to rise, at least, through the beginning of the next decade. If the EIA reference case projections turn out correctly, the United States would likely resume its role as a growing importer of oil, assuming no other market changes. Changing geopolitical relationships because of the current situation may prove short lived if oil production does not continue to increase. Despite having a cartel supplier trying to manipulate prices, the oil market remains robust and competitive.⁸⁷ Being a part of this market has helped many countries, both producers and consumers. As an example, when the United States needed petroleum products after Hurricanes Katrina and Rita in 2005, European countries were able to supply them from their strategic reserves. Similarly, when Japan shuttered its nuclear reactors after the Fukushima tragedy in 2011, the energy market reacted by sending more natural gas, coal, and oil resources to the country in order to satisfy energy demands. Unlike earlier periods, the United States is now a participant in energy agreements through the International Energy Agency to share the burden of supply disruptions on the world market. As part of its IEA membership, the United States maintains a Strategic Petroleum Reserve which can offset disruptions in imported supplies.

⁸⁵ EIA.

⁸⁶ Testimony by Amy Myers Jaffe, Executive Director of Energy and Sustainability, Graduate School of Management, Institute of Transportation Studies, University of California, Davis at the Senate Committee on Energy and Natural Resources' hearing, *U.S. Crude Oil Exports: Opportunities and Challenges*, January 30, 2014.

⁸⁷ OPEC tries to manipulate oil prices by controlling its production, but only Saudi Arabia maintains significant spare production capacity to adjust to immediate changes in market conditions, which is why it is referred to as the swing producer for oil. When production from other countries is disrupted Saudi Arabia may increase its production to maintain a target price, while it may cut production to make room for additional supplies from OPEC and non-OPEC countries. However, Saudi Arabia has used its position for its own ends and contrary to OPEC's goals, most notably when it crashed prices in 1986.

International Trade Policy

The potential exportation of U.S. crude oil may have implications for U.S. trade policy. The United States has undertaken certain obligations as a member of the World Trade Organization (WTO) and is a signatory to several regional and bilateral free trade agreements (FTAs).

As noted above, the United States licenses the export of crude oil under certain restrictive circumstances. The WTO generally discourages limitations on international trade such as import or export restraints. Underlying the WTO agreements are two basic principles: most-favored-nation (MFN) treatment and national treatment. MFN obligates a WTO member not to discriminate among the products of other member states. National treatment obligates a member not to treat another member's products as different from one's own. The General Agreement on Tariffs and Trade (GATT) Article XI, General Prohibition Against Quantitative Restraints, states:

No prohibition or restrictions other than duties, taxes or other charges made effective through quotas, import or export licenses or other measures, shall be instituted or maintained by any contracting party on the importation of any product of the territory of any other contracting party or on the exportation or sale for export of any product destined for the territory of any other contracting party.

However, some exceptions are available. Article XX provides a generalized exception that allows governments to restrict trade based on the conservation of exhaustible natural resources or the necessity to protect human health. However, these exceptions are subject to the provision that the objectives are not used as a disguised restriction on international trade or to arbitrarily discriminate between countries where the same conditions prevail. In this case, for example, restricting the export of crude oil may be dependent on a member's restriction of its own production.

The crude oil restriction may also be subject to the WTO's Agreement on Subsidies and Countervailing Measures (ASCM) if it, by limiting demand, drives down the price, thereby conferring a subsidy for domestic industry. This was one facet of a successful U.S. challenge to Chinese raw materials and rare earth export restrictions.

The United States is in negotiations on two multi-nation free trade agreements (FTAs): the Trans-Pacific Partnership (TPP) and the Transatlantic Trade and Investment Partnership (TTIP). TPP includes Australia, Brunei, Canada, Chile, Japan, Malaysia, Mexico, New Zealand, Peru, Singapore, and Vietnam. TTIP is a proposed agreement between the United States and the European Union. Countries in both of these negotiations may be interested in obtaining access to U.S. energy supplies. Both these agreements are directly relevant to exports of U.S. liquefied natural gas; according to statute it is in the national interest to approve LNG exports to FTA countries. There is no such exception for exports of crude oil; however, the EU reportedly has sought to put access to U.S. energy—including crude oil—on the agenda as a negotiating objective.

Environment

Potential environmental issues that could arise from the removal of crude oil export restrictions are dependent on the specific consequences that might ensue from removing such restrictions. However, these consequences, particularly the long-term effects, are uncertain.

A primary question for policy makers is the net effect on domestic oil production from removing the export restriction. As illustrated in **Figure 2**, EIA projects domestic production of LTO to increase dramatically in the near future. However, some observers have argued that the export restriction, coupled with current refinery configurations (discussed above), will effectively create a production ceiling for specific resources.⁸⁸ Assuming this is the case, the next question concerns magnitude: How much additional domestic production would occur if the crude oil export restriction is removed? Estimates for expected U.S. crude oil export volumes are uncertain and actual volumes will depend on multiple variables. As noted above in the “Price Effects” section, some estimate a potential excess of 500,000 bbl/d of light sweet crude oil by the 2015 to 2016 timeframe.

Assuming that lifting or modifying export restrictions would result in a substantial increase in domestic crude oil production—above what would otherwise occur—several environmental issues would likely receive some attention. These issues, discussed below, may include oil transportation, impacts related to oil extraction, and climate change.

Oil Transportation

A further increase in domestic crude oil production could amplify existing oil transportation concerns, which have received considerable attention. In particular, the current expansion of North American oil production has led to significant challenges in transporting crudes efficiently and safely using the nation’s legacy pipeline infrastructure. In the face of continued uncertainty about the prospects for additional pipeline capacity, and as a quicker, more flexible alternative to new pipeline projects, crude oil producers are increasingly turning to rail as a means of transporting crude supplies to U.S. markets. According to EIA data, the volume of crude oil carried by rail increased by 423% between 2011 and 2012.⁸⁹

While oil by rail has demonstrated benefits with respect to the efficient movement of oil from producing regions to market hubs, it has also raised significant concerns about transportation safety and potential impacts to the environment. The most recent data available indicate that railroads consistently spill less crude oil per ton-mile transported than other modes of land transportation.⁹⁰ Nonetheless, safety and environmental concerns have been underscored by a series of major accidents across North America involving crude oil transportation by rail.⁹¹

In addition, crude oil barge transportation may receive increased attention in light of the March 2014 oil spill in Galveston Bay, Texas.⁹² On March 22, 2014, a container ship collided with an oil

⁸⁸ See Amy Myers Jaffe (Institute of Transportation Studies, University of California, Davis), Testimony before the Senate Committee on Energy and Natural Resources, January 30, 2014; and Maria van der Hoeven (International Energy Agency), “US must avoid shale boom turning to bust,” *Financial Times*, February 2013.

⁸⁹ See EIA, Refinery Capacity Report, Table 9, June 2013. Note that this dataset indicates only the mode used for the last leg of such shipments. Some shipments may involve multiple modes, such as rail to barge.

⁹⁰ See CRS Report R43390, *U.S. Rail Transportation of Crude Oil: Background and Issues for Congress*, by John Frittelli et al. See also, CRS Report R43401, *Crude Oil Properties Relevant to Rail Transport Safety: In Brief*, by Anthony Andrews.

⁹¹ Ibid.

⁹² On March 22, 2014, a container ship collided with an oil barge, releasing approximately 168,000 gallons of oil, closing the Port of Houston. For more information, see U.S. Coast Guard updates at <http://www.uscgnews.com> and the National Oceanic and Atmospheric Administration website at <http://response.restoration.noaa.gov/oil-and-chemical-spills/oil-spills/kirby-barge-oil-spill-houstontexas-city-ship-channel-port-bolivar>.

barge, releasing approximately 168,000 gallons of oil into the bay and closing the Port of Houston.

As with rail transport, crude oil transportation by barge has increased substantially in recent years (by 53% between 2011 and 2012).⁹³ However, the same dataset cited above indicates that tank vessels and barges consistently spill less crude oil per ton-mile transported than other modes of oil transportation.⁹⁴ Nonetheless, spills from barges and tankers often occur in locations that may be particularly vulnerable to oil contamination.

Oil Extraction

Based on the geology of LTO, hydraulic fracturing (“fracking”) is often required to extract the resource. While the use of high-volume hydraulic fracturing has enabled the oil and gas industry to markedly increase domestic production,⁹⁵ questions have emerged regarding the potential impacts this process may have on both air quality and groundwater quality—particularly on private wells and drinking water supplies. The debate over the groundwater contamination risks associated with hydraulic fracturing has been fueled in part by the lack of scientific studies to assess the practice and related complaints.⁹⁶ These issues could receive additional attention if LTO extraction were to increase, due to a change in the U.S. crude oil export policy.

Climate Change

Some environmental groups want to keep the crude oil export restrictions in place for climate change reasons.⁹⁷ They argue that lifting the export restrictions would lead to increased crude oil development, which could potentially alter the “global carbon budget.” The global carbon budget is a scientifically estimated maximum amount of net worldwide greenhouse gases that could be emitted without exceeding a proposed temperature target of 3.6°F above pre-industrial levels (a 2°C target). Some consider that such a temperature target could avoid the worst effects of greenhouse-gas induced climate change, and it has been agreed as a political consideration in international negotiations to address climate change under the United Nations Framework Convention on Climate Change. Assuming this estimation is correct, all countries’ emissions (net of any sequestration or “sinks”) would have to stay within the carbon budget to avoid exceeding the 2°C temperature cap.

However, the degree to which a change in crude oil export policy would impact the carbon budget is beyond the scope of this report. Moreover, there is no political agreement in the United States on a domestic carbon budget, on the appropriateness of the global 2°C target, or on the validity of any target.

⁹³ See EIA, Refinery Capacity Report, Table 9, June 2013.

⁹⁴ See CRS Report R43390, *U.S. Rail Transportation of Crude Oil: Background and Issues for Congress*, by John Frittelli et al.

⁹⁵ Hydraulic fracturing is used for oil and/or gas production in all 33 U.S. states where oil and natural gas production takes place.

⁹⁶ For further discussion, see CRS Report R41760, *Hydraulic Fracturing and Safe Drinking Water Act Regulatory Issues*, by Mary Tiemann and Adam Vann.

Policy Options

In light of the considerations discussed above, and as the debate about exporting crude oil evolves, various proposals might emerge that fall within a spectrum of policy options that Congress may choose to consider. At one end of the spectrum are calls to lift export restrictions entirely. At the other end are calls to keep, maintain, and possibly expand current export restrictions. Additionally, there are various proposals to ease crude oil export restrictions on a limited basis. The following sections examine some policy options that have been proposed or discussed.

Lift Existing Restrictions

One policy option that Congress may consider is to introduce legislation that amends EPCA. Legislation that modifies EPCA, and other export-limiting statutes, may be the most straightforward means of lifting crude oil export restrictions.⁹⁸ However, some Members of Congress have called on the executive branch to use its existing powers to either lift or ease current export restrictions.⁹⁹ For more information about executive branch powers related to crude oil export restrictions, see the text box below titled “Could the Executive Branch Amend or Eliminate Crude Oil Export Restrictions Absent Legislation?”

Should export restrictions be lifted entirely, U.S. oil producers would have access to global markets, domestic and international prices would likely converge to some degree, and domestic crude oil production may increase if the economics are justified. While this scenario might potentially benefit crude oil producers, some U.S. refineries may be negatively affected as a result of reducing regional crude oil price discounts. Additional crude oil production may also result in environmental concerns associated with expanded extraction, transport, and consumption. While unrestricted crude oil exports—all else being equal—may be expected to put downward pressure on global crude prices and domestic gasoline prices, whether actual prices will be lower is uncertain. Global crude oil prices are determined by a number of factors that are not controlled by U.S. policy makers (e.g., supply disruptions, Saudi Arabia and OPEC decisions, and emerging demand from Asia). Ultimately, effects from crude oil exports on prices, the environment, and other considerations will be a function of the volume of crude oil that is produced and exported and will be further affected by the actions of other players in the global oil industry.

⁹⁸ EPCA is one law that restricts the export of crude oil. Other statutes include the Mineral Leasing Act, Outer Continental Shelf Lands Act, and the Naval Petroleum Reserves Production Act.

⁹⁹ U.S. Senator Lisa Murkowski, “A Signal to the World: Renovating the Architecture of U.S. Energy Exports,” January 7, 2014.

Could the Executive Branch Amend or Eliminate Crude Oil Export Restrictions Absent Legislation?

Interest in reducing or eliminating existing restrictions on the export of crude oil has focused attention on the most expeditious legislative and administrative tools to accomplish this end. The most determinative means by which to accomplish this would arguably be the amendment or repeal of the current language in EPCA directing the President to “promulgate a rule prohibiting the export of crude oil” absent a determination that the export be consistent with the national interest and the purposes of EPCA.¹⁰⁰ However, the executive branch may have some options available to it even if Congress does not take this action.

First, BIS could amend the short supply control regulations restricting the export of crude oil. The statute mandates only that exemptions to the general prohibition be granted if an export is “consistent with the national interest and the purposes of [EPCA].”¹⁰¹ The restrictive language found at 15 C.F.R. §754.2(b)(2) could be amended to except additional types of exports from the general prohibition so long as BIS finds the change to be in the national interest and consistent with EPCA.¹⁰² In order to change the pertinent regulations, BIS would have to follow the rulemaking procedures under the Administrative Procedure Act.¹⁰³

Additionally, BIS could approve more applications to export crude oil pursuant to the “case by case” review authorized by 15 C.F.R. §754.2(b)(2). Although the regulations do note that “generally” only certain kinds of narrowly tailored exports will be authorized, the regulations also note that “BIS will consider all applications for approval,” suggesting the possibility that exports that do not fit the criteria outlined in that section may nevertheless be licensed by the agency. If BIS finds that an increase in the types of exports of crude oil is in the national interest and consistent with EPCA, the agency is permitted to grant approval of those exports under the existing regulations that provide for case-by-case review.

However, it appears that BIS could not repeal the regulations entirely. As with all agencies, BIS cannot take any action beyond the scope of the statutory authority granted to it by Congress.¹⁰⁴ Because EPCA states that the President, through BIS, “shall ... promulgate a rule prohibiting the export of crude oil ... produced in the United States,”¹⁰⁵ BIS must have a rule in place that conforms with the statute—BIS would violate the statute if it simply repealed its regulations that impose a general prohibition on the export of crude oil. If BIS decided to repeal the regulation, any party aggrieved by the agency’s decision would be permitted to challenge the action in court.¹⁰⁶

Finally, as discussed above, the crude oil export restrictions are administered by BIS pursuant to a statute (EAA) that has expired, but continues to be effective due to annual executive orders renewing its provisions. The President could reverse those directives via another executive order, or opt to not issue a new order when the current one expires. However, this could create a number of practical problems, as it would nullify federal authority to conduct all export control operations set forth in the EAA. Also, while allowing the effectiveness of the EAA provisions to lapse would prevent administration of the BIS export license requirements, it would still leave in place the mandate of EPCA to restrict crude oil exports, a mandate that the Administration would be required to address.

Maintain Current Restrictions

Congress could also do nothing, thereby maintaining the requirement for the President to limit U.S. crude oil exports. According to supporters of this position, maintaining crude oil export

¹⁰⁰ Repealing this language would not affect the restrictions on certain kinds of exports found in the MLA, OCSLA and NPRPA.

¹⁰¹ 42 U.S.C. §6212(b)(1).

¹⁰² In addition, any new rule or amendment to the existing rule would also have to be considered a reasonable interpretation of the statutory language. See, e.g., *Motor Veh. Mfrs. Ass’n v. State Farm Ins.*, 463 U.S. 29 (1983).

¹⁰³ 5 U.S.C. §§551 *et seq.*

¹⁰⁴ See, e.g., *Louisiana Public Service Comm’n v. FCC*, 476 U.S. 355 (1986).

¹⁰⁵ 42 U.S.C. §6212(b)(1).

¹⁰⁶ 5 U.S.C. §§701, 702.

restrictions is warranted since the United States is, and will be, reliant on imports, and crude oil price discounts in the United States will be eliminated as domestic and global prices converge.¹⁰⁷

Should existing export restrictions remain in place, there may be several potential outcomes to consider. LTO production is expected to continue growing in the short/medium term and existing refinery configurations may result in an oversupply of certain types of crude oil in specific locations (e.g., Texas). While refineries can adjust their processes to accommodate changing crude oil qualities, they will likely make the necessary capital investments to do so only if the economics are warranted. Lower, or discounted, LTO prices would be an economic consideration—along with the expected longevity of price discounts—for refiners when making capital investment decisions. Lower/discounted oil prices may result in less LTO production from certain fields. However, the price discount needed to motivate refiners to make capital investments—and whether the price discount would be large enough to markedly reduce oil production—is uncertain. Nevertheless, maintaining current export restrictions may result in some oil producers receiving lower prices for oil produced. Lower prices may result in less U.S. oil production, and therefore less economic development associated with oil production. However, discounted crude oil prices in certain areas may also enable some refineries to operate profitably, especially those in locations that benefit from price discounts.

Modify Restrictions

Between lifting oil export restrictions altogether and maintaining them in their current form are a variety of policy options that might be considered. Some examples of such policies might include the following:

- ***Exempt LTO from export restrictions:*** The increase in LTO production appears to be one of the underlying dynamics motivating exports. As a result, crude oil with a certain quality characteristic or crude oil that is produced in specific locations might be exempted from export restrictions. The President has some powers to exempt certain crude oil exports if doing so is determined to be in the national interest. Exempting exports of certain types of crude from specific locations has occurred in the past. In 1992, then-President George H. W. Bush issued an executive order allowing 25,000 bbl/d of California heavy crude to be exported.
- ***Remove “lease condensate” from the BIS crude oil definition:*** As discussed in this report, lease condensate is an aspect of the crude oil export debate that is receiving attention due to increased production of extra-light hydrocarbons. Removing the term “lease condensate” from the crude oil definition may result in some of that material being exported, thereby addressing some of the apparent oversupply, and price discount, issues that may emerge in the Gulf of Mexico region. However, crafting a definition for lease condensate may present some challenges, as there is not an industry standard for this material.

¹⁰⁷ During the 113th Congress, Senators Markey and Menendez sent multiple letters to the President and members of the Administration arguing that crude oil export restrictions should remain in place and should not be modified. Content and analysis contained in letters from Senators Markey and Mendez include (1) keeping U.S. crude oil in country and maintaining price discounts, December 16, 2013, (2) opposing attempts to use the World Trade Organization as a catalyst for changing U.S. export laws, December 3, 2013, and (3) Commerce Department authority limits and underlying export laws, January 30, 2014.

- ***Allow crude oil exports for a limited period of time:*** EIA 2014 reference case LTO projections indicate that production may reach an upper limit by 2019 and then start to decline. While actual LTO production levels are uncertain, one policy option may be to allow crude oil exports only for a defined period of time—five years, for example—after which the domestic production and export situation could be reassessed.

There are a number of other options for modifying existing restrictions that might be considered. Each option could impact the market and individual stakeholders in different ways. Congress may choose to study and analyze various considerations associated with efforts to modify crude export restrictions.

Appendix A. Crude Oil Export Applications Approved by BIS
